

Introspector

Team: Constantin-Cosmin Alexa and Mihai-Adrian Tecliceanu

Project description

The Introspector project is a hot patching Android application which can control other apps inside of the phone, similar to what Frida can do, combined with Cheat Engine, everything in a security researcher's phone. This project targets security researchers in providing better tooling when trying to check an Android application but a computer is not available in the near vicinity.

It may need the requirement for the researcher's phone to be rooted, but it's expected since the user is a researcher. ☺

Motivation

Security researchers often are more on their phones than their computers, why waste that time when you could do some useful security research on your own apps.

This also benefits potential future security researchers in developing countries, an Android phone is far more accessible, compared to a laptop/computer.

Our main competition would be LuckyPatcher, it is a closed source application, we would like to change that.

Goals of the project

We're setting the following goals:

- Implementation of a cheat engine feature
- Source code of other apps to be accessible similar with jadx
- Frida capability to modify the other app's implementation
